

Subnational Under-five and Neonatal Mortality Estimates, 2000–2021

Estimates developed by the United Nations Inter-agency Group for Child Mortality Estimation (UN IGME)

Acknowledgments

The brochure was prepared at UNICEF headquarters by David Sharrow, Lucia Hug, Yang Liu and Danzhen You on behalf of the United Nations Inter-agency Group for Child Mortality Estimation (UN IGME). The model for subnational estimation and this set of estimates were developed and produced by Jon Wakefield, Alana McGovern, Jessica Godwin, Zehang Richard Li, Katie Paulson, Julianne Meisner, Taylor Okonek, Yunhan Wu, Ziyu Liu, Peter Gao, Johnny Paige, Aja Sutton, Geir-Arne Fuglstad, Andrea Riebler, Qianyu Dong, Ziyu Jiang, Orvalho Augusto, Victoire Michal, Connor Gascoigne, Andrea Boskovic, and Avi Kenny.

Estimates were developed in consultation with countries. Special thanks to the many government agencies in countries for providing feedback and to UNICEF country office colleagues for support during the country consultation process.

Thanks to the UN IGME, led by UNICEF and including members from the World Health Organization, the World Bank Group and the United Nations Population Division, and to the Technical Advisory Group of the UN IGME, comprised of leading academic scholars and independent experts in demography and biostatistics, for providing support and technical guidance on methods for subnational estimation. Thanks to Daniele Olivotti, Alberto Sibleau, Yves Jaques and Jan Burdziej of UNICEF for providing technical support.

Great appreciation also goes to the Bill & Melinda Gates Foundation and the United States Agency for International Development (USAID) for supporting the child mortality estimation work of the UN IGME and UNICEF.

Naomi Lindt edited the brochure.
Jiayan He laid out the brochure.

Subnational under-five mortality rate (U5MR) and neonatal mortality rate (NMR) estimates, 2000–2021, provide critical insight into mortality rates and trends at the level at which health interventions and decisions on resource allocation are typically made

Under-five mortality rate at administrative level 1 and administrative level 2, 2021

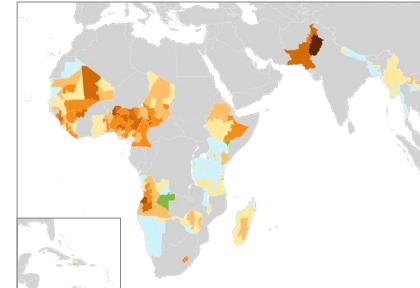

Administrative level 1
422 divisions across
31 countries

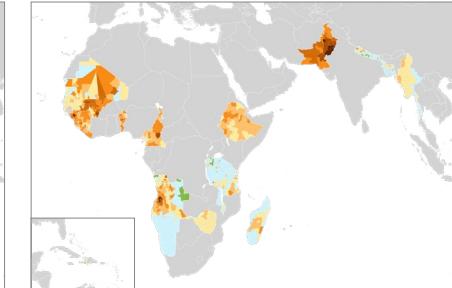

Administrative level 2
1,751 divisions across
24 countries

Neonatal mortality rate at administrative level 1 and administrative level 2, 2021

Administrative level 1
397 divisions across
29 countries

Administrative level 2

Subnational estimates can help target interventions where most needed

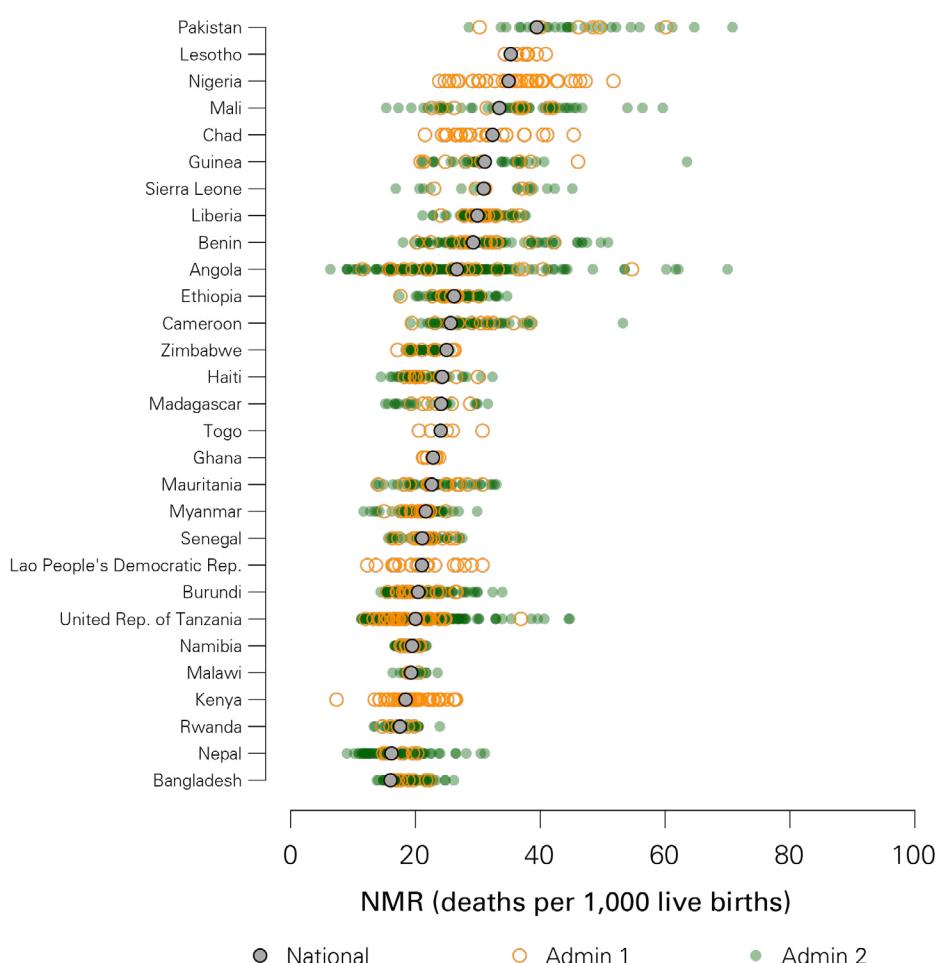

In Nigeria, where the national under-five mortality rate for 2021 was 111 deaths per 1,000 live births, rates at administrative level 1 ranged from a low of 52 deaths per 1,000 live births to a high of 253 deaths per 1,000 live births in 2021.

In Angola, the national neonatal mortality rate was 27 deaths per 1,000 live births, while subnational rates at administrative level 2 ranged from a low of 6 to a high of 70 deaths per 1,000 live births in 2021.

Under-five mortality rate estimates by administrative 1 and administrative 2 divisions for 31 countries, 2021

Neonatal mortality rate estimates by administrative 1 and administrative 2 divisions for 29 countries, 2021

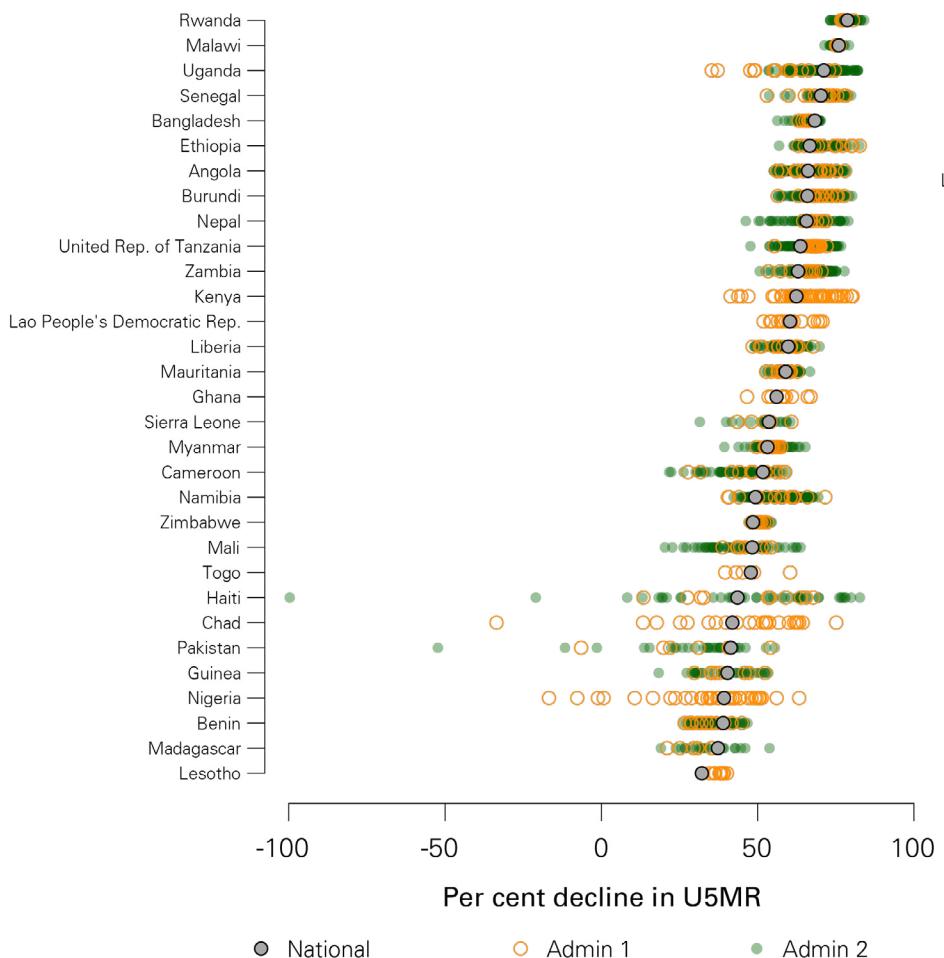

National progress in reducing under-five and neonatal mortality can obscure uneven subnational trends

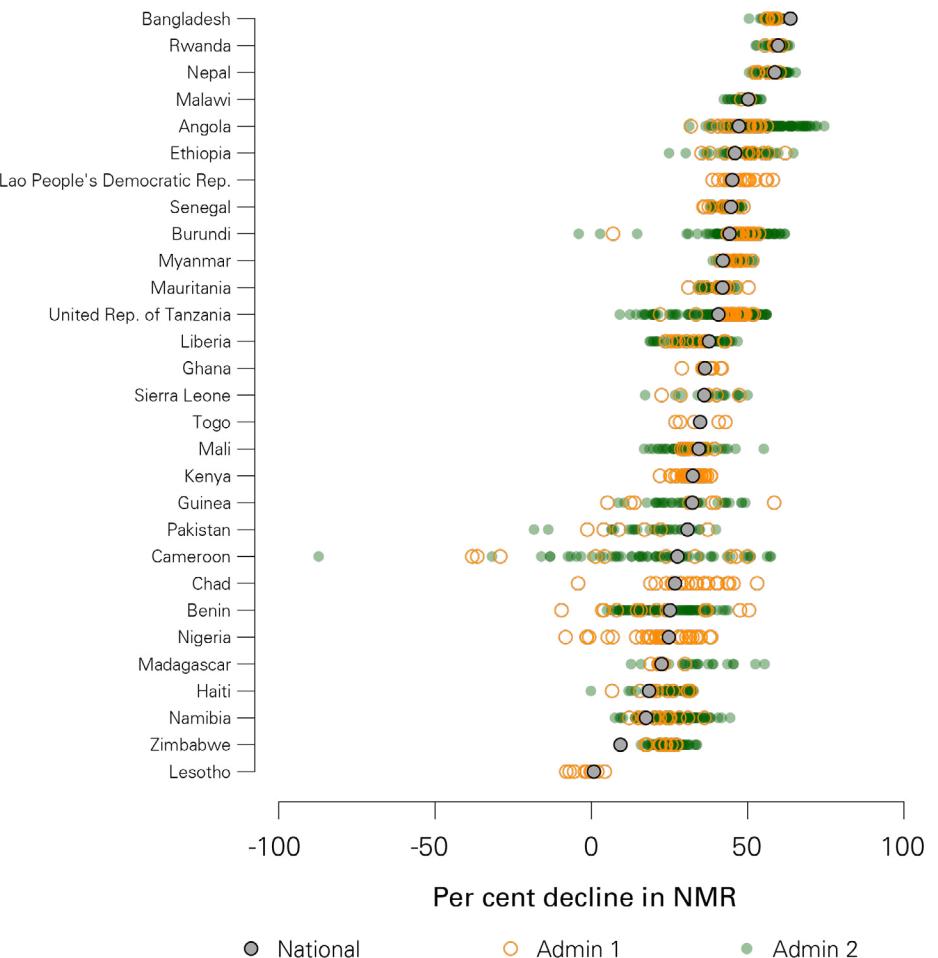

In Chad, the national under-five mortality rate has declined by 42 per cent since 2000, while the per cent decline within administrative level 1 divisions ranged from a high of 75 per cent to a low of -34 per cent (an increase since 2000).

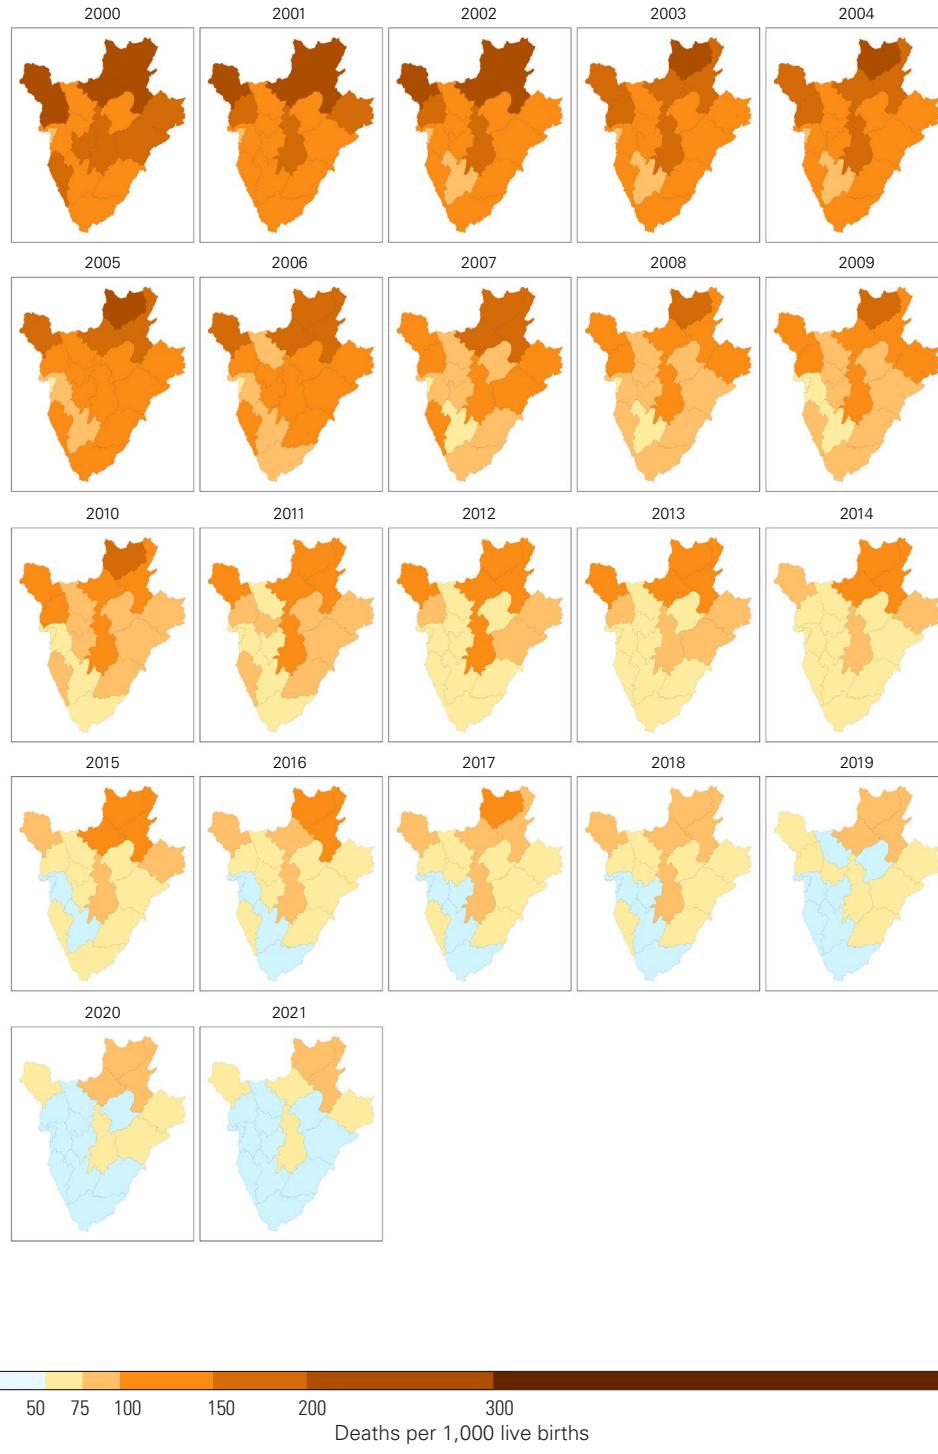

In Haiti, the national neonatal mortality rate has declined by 18 per cent since 2000, while the per cent decline within administrative level 1 divisions ranged from a high of 32 per cent to a low of just 7 per cent.

Percentage decline in the under-five mortality rate at administrative level 1 and administrative level 2 (where available) for 31 countries, 2000–2021

Percentage decline in the neonatal mortality rate at administrative level 1 and administrative level 2 (where available) for 29 countries, 2000–2021

Subnational regional variation in under-five mortality rates persists in some cases, even while all subnational areas see decline

In Burundi, mortality risk has remained lower in the southern provinces relative to the northern provinces, even while the national under-five mortality rate fell by 66 per cent since 2000 and all provinces (administrative level 1) saw a decline in under-five mortality since 2000.

Under-five mortality rate at administrative level 1 in Burundi, 2000-2021

NMR by administrative 1 area in Rwanda, 2000-2021

In 2000, NMR ranged from 33 to 49 deaths per 1,000 live births. By 2021, NMR ranged from 15 to 20 deaths per 1,000 live births.

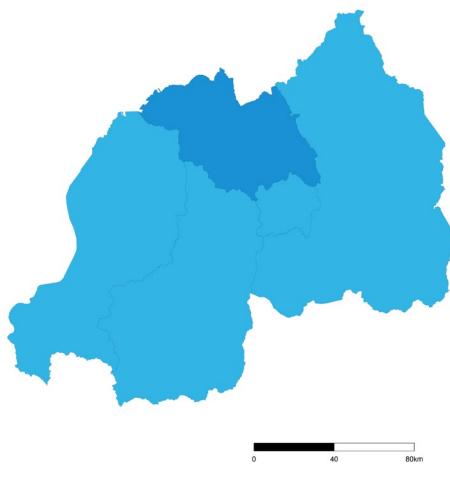

NMR by administrative 2 area in Rwanda, 2000-2021

In 2000, NMR ranged from 32 to 56 deaths per 1,000 live births. By 2021, NMR ranged from 13 to 24 deaths per 1,000 live births.

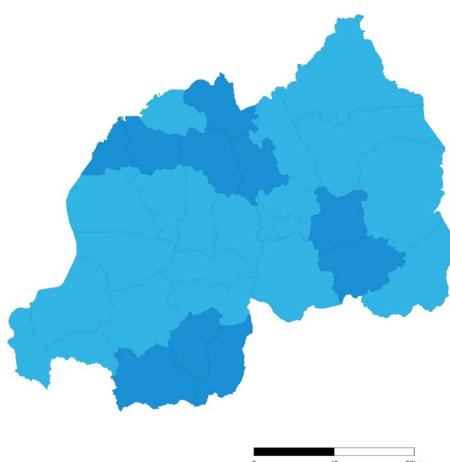

Percentage decline in administrative level 1 NMR 2000-2021 in Rwanda

The percentage decline in neonatal mortality at administrative level 1 ranged from a low of 56 per cent to a high of 61 per cent.

Percentage decline in administrative level 2 NMR 2000-2021 in Rwanda

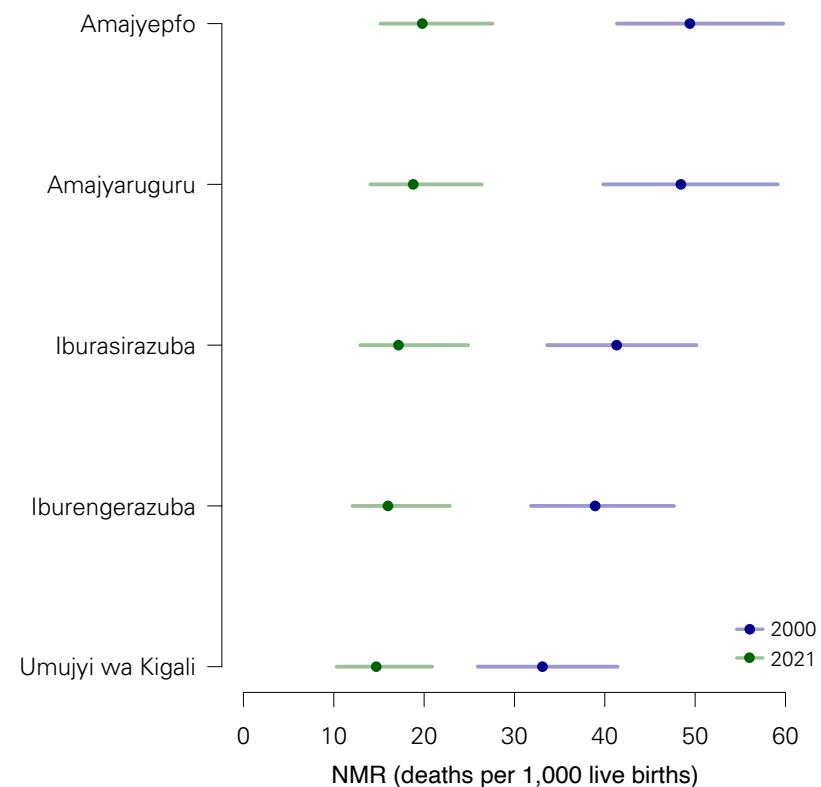

The percentage decline in neonatal mortality at administrative level 2 ranged from a low of 53 per cent to a high of 63 per cent.

NMR with 90 per cent uncertainty intervals (shaded bar) for administrative 1 areas of Rwanda, 2000 and 2021

In 2000, the risk of dying before reaching age 28 days for a child born in Amajyepfo, the highest mortality administrative level 1 area, was 1.5 times higher than in Umujyi wa Kigali, the lowest mortality area. In 2021, NMR in the highest mortality administrative level 1 area, Amajyepfo, was 1.3 times higher than in the lowest mortality area, Umujyi wa Kigali.

Note: The dots represent the median estimates, and the lines represent the 90 per cent uncertainty intervals.

Administrative boundaries are based on the GADM database of Global Administrative Areas, available at <https://gadm.org/>.

Technical notes

Subnational Estimation of Under-five Mortality Rates (U5MR) and Neonatal Mortality Rates (NMR): The BB8 Model

Estimating subnational variation in child mortality is of great importance to flag areas with high rates and to track progress towards targets such as the Sustainable Development Goals, which explicitly mention monitoring subnational child mortality. In the absence of vital registration systems, obtaining estimates at subnational levels—national level is denoted by Admin0, with increasingly granular subnational levels being denoted Admin1, Admin2, and so on—is a challenge, because the most reliable data in many countries come from household surveys, which are not generally designed to collect sufficient clusters to characterize U5MR at the Admin2 level, which is the level at which health interventions and decisions on resource allocation are typically made.

Subnational U5MR and NMR are estimated for 2000-2021 using a BetaBinomial sampling model with:

1. Cluster-level modeling
2. Space-time smoothing
3. Urban-rural stratification
4. Bayesian inference
5. Overdispersion
6. Benchmarking to UN IGME national estimates
7. an HIV adjustment
8. Informative visualization.

Hence, the model is referred to as BB8.

To overcome sparse data problems, U5MR and NMR are modeled at the cluster-level directly using a Bayesian space-time model. Subnational U5MR and NMR are estimated using household survey data from Demographic and Health Surveys (DHS) and Multiple Indicator Surveys (MICS), which both typically use stratified two-stage

cluster sampling with strata that are urban/rural crossed with some set of geographical (often Admin1) areas.

Mortality risk is assumed to be similar at locations that are close together because of shared risk factors, thus the risk of mortality is assumed to have spatial structure. The model contains spatial terms to account for such structure.

The betabinomial distribution is used in the model since it appropriately characterizes the binary outcome (non-death/death) distribution and has an additional parameter to accommodate overdispersion or excess binomial variation.

For neonatal mortality, the model is,

$$Y_c | p_c \sim \text{Beta-binomial}(n_c, p_c, d), \text{ for } c=1, \dots, C$$

where Y_c is the number of deaths out of n_c births, and $p_c = p(s_c)$ is the probability of a death at location s_c for $c=1, \dots, C$ clusters. The parameter d allows for overdispersion and is related to the within-cluster correlation between the n_c different responses.

The probability is modeled as,

$$p(s_c) = \text{expit}(\alpha + S_{c[i]} + e_{c[i]})$$

for rural clusters c and

$$p(s_c) = \text{expit}(\gamma + S_{c[i]} + e_{c[i]})$$

for urban clusters c

where $S_{c[i]}$ and $e_{c[i]}$ are spatial and independent random effects, respectively, specified at the Admin2 level, which is indexed by i ; the notation $c[i]$ here should be read as the Admin2 area i that cluster c resides in. Hence, all clusters in Admin2 area i receive the same

random effects. The spatial terms are assumed to follow an intrinsic conditional autoregressive (ICAR) model¹. The latter is the most popular model for disease mapping in epidemiology, since it is straightforward to fit and has been shown in a multitude of studies to provide reliable estimates. The model is fit using the fast and accurate integrated nested Laplace approximation (INLA) approach². The separate intercept terms for urban (α) and rural (γ), along with the S_i and e_i terms, accommodate the stratified sampling.

Aggregation of the cluster probabilities to Admin2 area i is aided by the assumption of a constant spatial term within each Admin2 area. Specifically, the probability of a neonatal death in Admin2 area i is

$$p_i = q_i \text{expit}(\alpha + S_i + e_i) + (1-q_i) \text{expit}(\gamma + S_i + e_i)$$

where q_i is the probability of dying in a rural cluster in Admin2 area i . The probability q_i is taken as the proportion of children aged 0-4 who reside in the urban portion of area i . These proportions are estimated using data from WorldPop³.

For the U5MR and NMR estimation over time, the model is more complex since it is necessary to consider how the risks change over time and with age, in addition to space.

As with previous work^{4,5}, a discrete hazards model is assumed with 6 hazards for each of the age groups (in months): 0-1, 2-11, 12-23, 24-35, 36-47, 48- 59. A flexible random walk of order 2 (RW2) as the main temporal term is also assumed, with separate random walks for the age groups 0-1, 2-11, 12-59. This model carries out local linear smoothing using the previous two time periods (which correspond to years in the model). For the main spatial term an ICAR model is assumed. We also assume a space-time interaction. Depending on the country, either a RW2 and ICAR model are combined, or an autoregressive of order

1 (AR1) model and an ICAR are combined. The RW2, ICAR and AR1 models are described in more detail elsewhere⁶. The interaction terms allow local deviations from the main spatial and temporal patterns. All available, high quality survey data covering the estimation period, 2000-2021, were considered for model inclusion, however, because in some countries ignoring the urban/rural stratification can lead to bias, we have developed methods to adjust for the stratification. Currently, the methods are only available for surveys that use the same sampling frame, though this aspect will be revisited in future rounds of UN IGME subnational estimates.

Survey data are adjusted to account for mothers who have died from AIDS, and whose children are at greater risk of death using the same method used in the U5MR B3 model (See the explanatory notes 'Child and youth mortality trend series to 2021'⁷ for a description of the methods to generate national U5MR estimates with the B3 model (section 3) and a description of the HIV/AIDS adjustment (section 2.4)). In general, the B3 model uses more data (for example from censuses and vital registration systems, when available), thus the estimates are benchmarked to the B3 estimates at the national level, for consistency.

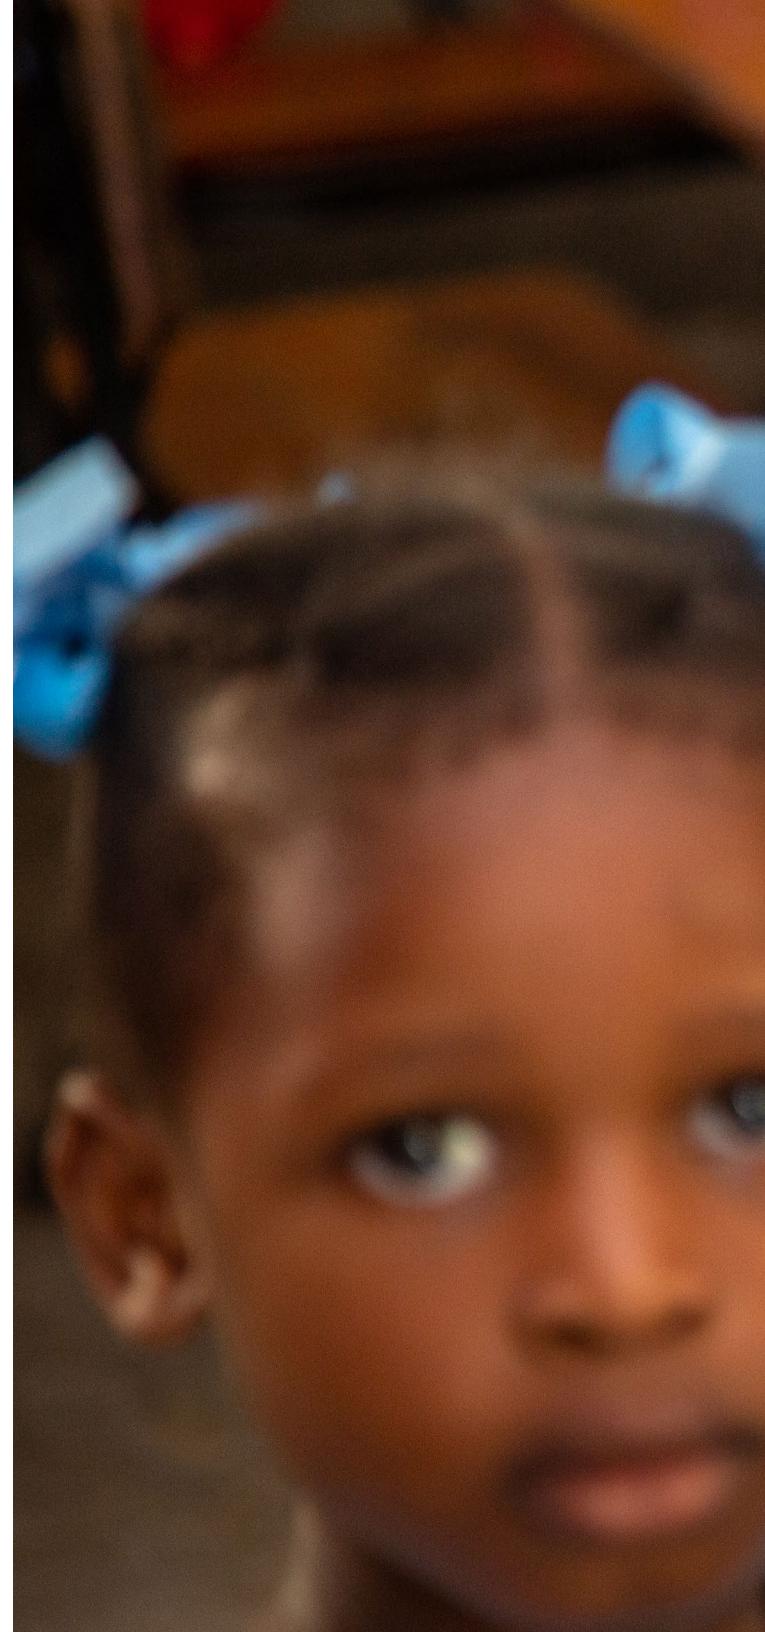

The model is fitted in the R programming environment using the [SUMMER package](#)⁸.

There are numerous ways to present and visualize summaries of the subnational estimates over time. It should be noted here that the subnational estimates also have uncertainty intervals via Bayesian inference, however they are not well conveyed on colour-coded maps. Estimates for all areas with uncertainty can be found at the UN IGME web portal, www.childmortality.org.

UN IGME under-five and neonatal mortality rates by subnational areas are produced in consultation with countries.
